### Introduction

The NKF K/DOQI guidelines [1] state the following: 1) AV fistulas have the lowest rate of thrombosis and require the fewest interventions, 2) cost of AV fistula use and maintenance is the lowest, 3) fistulas have the lowest rates of infection, and 4) fistulas are associated with the highest survival and lowest hospitalization rates. Indeed, a number of epidemiologic studies consistently demonstrate the reduced morbidity and mortality associated with greater use of AV fistulas for vascular access in maintenance hemodialysis. Finally, numerous studies demonstrate that the use of AV fistulas have the best 5-year patency rates and require the fewest interventions compared with other access types.

The Standardized Fistula Rate (SFR) was developed based on recommendations from the 2015 Vascular Access Technical Expert Panel charged with reviewing the existing vascular access measures and providing recommendations on revisions to better account for the complexity of factors influencing vascular access type. The summary report from the in-person TEP meeting can be found at LINK

This Standardized Fistula Rate (SFR) is intended to be jointly reported with the Long-term Catheter Rate measure. These two vascular access quality measures, when used together, consider Arterial Venous Fistula (AVF) use as a positive outcome and prolonged use of a tunneled catheter as a negative outcome. Use of an Arteriovenous Graft (AVG) is considered a neutral outcome and reflects the TEP consensus that AVF are the preferred access for most, but not all, patients on dialysis. With the growing recognition that some patients have exhausted options for an AVF or have comorbidities that may limit the success of AVF creation, joint reporting of the measures accounts for all three vascular access options. The SFR adjusts for patient factors where fistula placement may be either more difficult or not appropriate and acknowledges that in certain circumstances an AV graft may be the best access option. This paired incentive structure that relies on both measures (SFR, long-term catheter rate) reflects consensus best practice, and supports maintenance of the gains in vascular access success achieved via the Fistula First/Catheter Last Project over the last decade.

### Methods

### **Overview**

The SFR (NQF #2977) is a replacement of NQF #0257, Maximizing Placement of Arterial Venous Fistula. The measure specifications for SFR include a number of enhancements to the previous set of specifications for #0257. These enhancements reflect input from the 2015 Vascular Access Technical Expert Panel that was convened to review and provide recommendations for improving the previous set of vascular access measures (#0256 and #0257).

- Risk adjustment for factors that are associated with decreased likelihood of AV fistula success:
  - a. Diabetes
  - b. Heart diseases
  - c. Peripheral vascular disease
  - d. Cerebrovascular disease

- e. Chronic obstructive pulmonary disease
- f. Anemia (unrelated to ESRD/CKD)
- g. Non-Vascular Access-Related Infections
- h. Drug dependence
- 2. Inclusion of all eligible hemodialysis patients, not just Medicare beneficiaries, since the measure is now specified to be calculated from CROWNWeb.
- 3. Inclusion of patients in the first 90 days of dialysis, who were previously excluded, as this is a critical time for access planning/placement.
- 4. Only patients with an AVF using 2 needles (or an approved single needle device) are counted in the numerator. Fistula combined with another access type, such as a catheter is no longer counted, unlike the currently endorsed measure.
- 5. Exclusion criteria have been added to the measure for conditions associated with a limited life expectancy where an AVF may not be the appropriate choice for access (e.g. hospice, metastatic cancer, end stage liver disease, and coma/brain injury).

### **Data Sources**

Data was derived from an extensive national ESRD patient database, which is primarily based on the CMS Consolidated Renal Operations in a Web-enabled Network (CROWN) system. The CROWN data include the Renal Management Information System (REMIS), CROWNWeb facility-reported clinical and administrative data (including CMS-2728 Medical Evidence Form, CMS-2746 Death Notification Form, and CMS-2744 Annual Facility Survey Form data), the historical Standard Information Management System (SIMS) database (formerly maintained by the 18 ESRD Networks until replaced by CROWNWeb in May 2012), the National Vascular Access Improvement Initiative's Fistula First Catheter Last project (in CROWNWeb since May 2012), Medicare dialysis and hospital payment records, transplant data from the Organ Procurement and Transplant Network (OPTN), the Nursing Home Minimum Dataset, the Quality Improvement Evaluation System (QIES) Workbench, which includes data from the Certification and Survey Provider Enhanced Report System (CASPER), the Dialysis Facility Compare (DFC) and the Social Security Death Master File. The database is comprehensive for Medicare patients. Non-Medicare patients are included in all sources except for the Medicare payment records. CROWNWeb provides tracking by dialysis provider and treatment modality for non-Medicare patients. Information on hospitalizations is obtained from Part A Medicare Inpatient Claims Standard Analysis Files (SAFs), and past-year comorbidity is obtained from multiple Part A types (inpatient, home health, hospice, skilled nursing facility claims) and Part B outpatient types of Medicare Claims SAFs.

CROWNWeb, Medicare Claims and the CMS Medical Evidence form 2728 are used as the data sources for establishing the denominator. CROWNWeb is the data source for establishing the numerator. Medicare claims and the CMS Medical Evidence form 2728 are data sources for the risk adjustment factors. Medicare claims and CROWNWeb are used for the exclusion criteria.

### **Outcome Definition**

The numerator is the adjusted count of adult patient-months using an AVF as the sole means of vascular access as of the last hemodialysis treatment session of the month.

An AVF is considered in use if the CROWNWeb "Access Type IDs" of 14 or 22 has been recorded for a given month, where "14" represents AV fistula only (with 2 needles) and "22" represents AV fistula only with an approved single needle device.

### **Denominator Definition**

All patients at least 18 years old as of the first day of the reporting month who are determined to be maintenance hemodialysis patients (in-center and home HD) for the entire reporting month at the same facility.

For each patient, we identify the dialysis provider at each month using a combination of Medicare-paid dialysis claims, the Medical Evidence Form (Form CMS-2728), and data from CROWNWeb. These sources are used to identify patients that are on in-center or home hemodialysis for the entire reporting month. Patients are required to have been treated by the same facility for the complete month in order to be assigned to that facility for the reporting month.

The monthly patient count at a facility includes all eligible prevalent and incident patients. The number of patient-months over a time period is the sum of patients reported for the months covered by the time period. An individual patient may contribute up to 12 patient-months per year.

## **Risk Adjustment**

### **Choosing Adjustment Factors**

Although there have been significant gains in the proportion of dialysis patients that have an AV fistula, it is generally recognized that some patients on hemodialysis will need to have an AV graft or even a catheter. As evidence, the Fistula First Catheter Last AV fistula target at the facility level is 68%, rather than 100%, which recognizes that some patients may require a different type of access. A growing number of studies report that creating AVF in some patients is less likely to be successful in the presence of certain comorbidities [2-4]. In addition, certain patient groups may have less incremental benefit from an AV fistula relative to an AV graft.

Given that there is variation in the burden of comorbidities between different facilities, adjusting for these factors when calculating an AV fistula rate implicitly recognizes that some patients are more likely to have AV grafts, independent of facility action. Drawing on several studies detailing particular patient characteristics associated with a decreased likelihood of successful AV fistula creation, the final 2015 Vascular Access TEP recommendations informed the evaluation and selection of the clinical and patient risk factors for the SFR. The covariates in the final model represent a combination of those recommended by the TEP for inclusion as well as factors that empiric analyses indicated were predictive of AV fistula use. Final decisions of the risk factors were based on both the clinical and statistical association with the lower likelihood of fistula use in patients with these risk factors, and the assessment by the 2015 Vascular Access TEP that these factors were not likely to be associated with facility care.

Risk adjustment began with a large set of patient characteristics, including demographics, comorbidities at ESRD incidence and/or in the past 12 months, and other patient characteristics (listed in the next section). Factors considered appropriate were then investigated with statistical models to determine if they were related to AVF use. Factors related to the SFR were also evaluated by the TEP for face validity prior to inclusion.

The SFR risk adjustment is based on a multivariate logistic regression model. The model adjusts for age, BMI at incident, nursing home status, nephrologist's care prior to ESRD, duration of ESRD, diabetes as primary cause of ESRD, and comorbidities. Although covariates are assumed to have the same effects across facilities, the adjustment model is fitted with different facility effects (through facility-specific intercept terms), which provides valid estimates even if the distribution of adjustment variables differs across facilities.

We used two data sources to collect comorbidity information: CMS-2728 (collected at ESRD incidence only) and Medicare claims filed within the previous12 months. The covariates for comorbidities included in the final model take a value of 1 if there was any evidence of the comorbidity condition in either the CMS-2728 form or Medicare claims, otherwise a value of 0 was applied (no comorbidity). In our analyses on comorbidities we also used an indicator to identify patients with < 6 months of Medicare coverage in the past 12 months to indicate patients without a sufficient claims history to determine the presence of comorbidities from Medicare claims. Additionally, some patient characteristics or comorbidities are only available in CMS-2728, some are only available in Medicare claims, and some are available from both sources. We considered the condition to be present if it was noted in either the CMS-2728 form, or Medicare claims, or both. Table 1 shows that almost all of the comorbidities had a statistically significant association with AVF use.

### **Adjustment in SFR**

The SFR measure is a directly standardized percentage, in that each facility's percentage of AVF use is adjusted to the national distribution of covariates (risk factors) (with 'national' here referring to all-facilities-combined). The SFR for facility is an estimate of what the facility's percentage of AVF would equal if the facility's patient mix was equal to that of the nation as a whole. The measure is adjusted for patient demographic and clinical characteristics based on a logistic regression model. This model includes the facility indicators and assumes that the regression coefficients of risk factors are the same across all facilities. The common risk effects are assumed in order to improve computational stability in estimating facility-specific effects.

The patient characteristics included in the logistic regression model as covariates are:

- Age
- BMI at incidence
- Nursing home status in previous year
- Nephrologist's care prior to ESRD
- Duration of ESRD
- Inability to ambulate/transfer at ESRD incidence (CMS-2728 form)
- Comorbidities either at ESRD incidence (CMS-2728 form) or prevalent comorbidities based on Medicare claims filed in prior 12 months namely, Diabetes, Heart diseases, Peripheral vascular disease, Cerebrovascular disease, Chronic obstructive pulmonary disease, Anemia (unrelated to ESRD/CKD), Non-Vascular Access-Related Infections, and Drug dependence.
- Indicator for Medicare coverage for at least 6 months during the past 12 months

### **Exclusions**

Exclusions that are implicit in the denominator definition include:

- Pediatric patients (<18 years old)</li>
- Patients on Peritoneal Dialysis
- Patient-months with in-center or home hemodialysis for less than a complete reporting month at the same facility

In addition, the following exclusions are applied to the denominator:

- Patients with a catheter that have limited life expectancy:
- Patients under hospice care in the current reporting month
- Patients with metastatic cancer in the past 12 months
- Patients with end stage liver disease in the past 12 months
- Patients with coma or anoxic brain injury in the past 12 months

Determination of peritoneal dialysis treatment modality is derived from a combination of Medicare-paid dialysis claims, the Medical Evidence Form (Form CMS-2728), and data from CROWNWeb. These sources also determine patient assignment to the facility. Patients not treated by the facility for the entire month are excluded for that reporting month.

The patient's age is determined by subtracting the patient's date of birth from the first day of the reporting month. Patients that are <18 years old as of the first day of the reporting month are excluded. For the exclusion of catheter patients with limited life expectancy, catheter use in the reporting month is defined as the CROWNWeb "Access Type ID" having any of the following values: (16,18,19,20,21,"·"), where Access\_Type\_ID "16" represents AV Fistula combined with a Catheter, "18" represents AV Graft combined with a Catheter, "19" represents Catheter only, "20" represents Port access only, "21" represents other/unknown, and "·" represents missing.

Hospice status is determined from a separate CMS file that contains final action claims submitted by Hospice providers. Once a beneficiary elects Hospice, all Hospice related claims will be found in this file, regardless if the beneficiary is in Medicare fee-for-service or in a Medicare managed care plan. Patients are identified as receiving hospice care if they have any final action claims submitted to Medicare by hospice providers in the current month.

Diagnoses of metastatic cancer, end stage liver disease, or coma in the past 12 months were determined from Medicare claims. Medicare claim types include inpatient admissions, outpatient claims (including dialysis claims) and physician services. Claims from providers, such as laboratories that report diagnosis codes when testing for the presence of a condition are excluded. A detailed list of ICD-9/ICD-10 diagnostic codes used to identify these comorbidities is included in the appendix.

## **Calculating SFR**

Let  $n_i$  be the number of patients treated at the  $i^{th}$  facility (for i = 1,...,F),  $x_{ijm}$  be a vector of the patient characteristics, and  $p_{ijm}$  be the probability of dialyzing with an AVF for the  $j^{th}$  patient in the  $i^{th}$  facility (for  $j = 1,...,n_i$ ) in the  $m^{th}$  month. To estimate facility effects, we use the following logistic regression model

$$logit(p_{ijm}) = \alpha_i + \beta' x_{ijm}$$

and denote the resulting estimates of facility effects  $(\alpha_1,...,\alpha_F)$  by  $(\alpha_1,...,\alpha_F)$  and the estimates of the risk effects  $\beta$  by b.

$$SFR_k = \sum_i \sum_j \sum_m exp(a_k + b'x_{ijm}) / \{1 + exp(a_k + b'x_{ijm})\} / n$$
,

where n = total number of patient-months included in the overall study sample.

### **Missing Data**

Patients with a missing vascular access type are counted in the denominator, but not the numerator. For comorbidities, if the patient had missing comorbidity values both in the preceding 12 months of Medicare claims and in the Medical Evidence Form for the corresponding comorbidity, we assume this patient did not have the comorbidity in that reporting month. The same methodology is applied to the comorbidity exclusions and the hospice exclusion.

## **Testing Results**

In the table below, we list results from the adjusted model described above. For a given covariate, the regression coefficient represents the logit of the rate. We also report the odds ratio for each covariate. With a few exceptions (youngest age group, other heart diseases and anemia), all main effects are statistically significant at the 0.05 level.

Table 1. Model Coefficients and Odds Ratios, Data Year 2014

Covariate	Coefficient	Odds Ratio	P-value
Age			
18-<25	0.073	1.076	0.530
25-<59	0.087	1.091	0.000
60-<75	reference		
75+	-0.202	0.817	<.0001
ВМІ			
underweight(< 18.5)	-0.215	0.806	0.001
normal(18.5 - 24.9)	reference		
overweight(>24.9)	0.054	1.055	0.026
Nursing home status*	-0.321	0.726	<.0001
Nephrologist's Care prior to ESRD*	0.257	1.293	<.0001
Duration of ESRD			
<1 year	-1.171	0.310	0.000

Covariate	Coefficient	Odds Ratio	P-value
1-<5 years	reference		
5-<9 years	-0.234	0.792	0.000
9+	-0.602	0.548	0.000
Primary Cause of ESRD			
Diabetes	-0.053	0.948	0.034
Other	reference		
Comorbidities*			
Diabetes (NOT as primary cause of ESRD)	-0.121	0.886	<.0001
Heart Failure	-0.046	0.955	0.038
Other Heart Diseases	-0.037	0.963	0.114
Peripheral Vascular Disease	-0.340	0.712	<.0001
Cerebrovascular Disease	-0.113	0.893	<.0001
Chronic Obstructive Pulmonary Disease	-0.083	0.921	0.001
Drug Dependence	-0.207	0.813	<.0001
Inability to ambulate/transfer	-0.497	0.609	<.0001
Anemia (unrelated to ESRD/CKD)	-0.049	0.952	0.228
Non-Vascular Access-Related Infections: Pneumonia/Hepatitis/HIV/Tuberculosis	-0.286	0.751	<.0001
Less than 6-months of Medicare coverage in past 12 months	-0.447	0.640	<.0001
* 'No' was used as reference.			

The C-statistic (also known as the Index of Concordance) was 0.70. This indicates that the model correctly ordered 70% of the pairs of patient-months that were discordant with respect to the response variable.

# **Reliability Testing**

We used January 2014 – December 2014 CROWNWeb data to calculate facility-level annual performance scores. The NQF-recommended approach for determining measure reliability is a one-way

analysis of variance (ANOVA), in which the between-facility variation  $(\sigma_b^2)$  and the within-facility variation  $(\sigma_{t,w}^2)$  in the measure is determined. The inter-unit reliability (IUR) measures the proportion of the total variation of a measure (i.e.,  $\sigma_b^2 + \sigma_{t,w}^2$ ) that is attributable to the between-facility variation, the true signal reflecting the differences across facilities. We assessed reliability by calculating inter-unit reliability (IUR) for the annual performance scores. A small IUR (near 0) reveals that most of the variation of the measure between facilities is driven by random noise, indicating the measure would not be a good characterization of the differences among facilities, whereas a large IUR (near 1) indicates that most of the variation between facilities is due to the real difference between facilities.

Here we describe our approach to calculating IUR. Let  $T_1,...,T_N$  be the Standardized Fistula Rate (SFR) for N facilities. Since the variation in  $T_1,...,T_N$  is mainly driven by the estimates of facility-specific intercepts  $(\alpha_1,...,\alpha_N)$ , we use their asymptotic distributions to estimate the within-facility variation in SFR. Applying the delta method, we estimate the variance of  $T_i$  and denote the estimate as  $S_i^2$ . Calling on formulas from the one-way ANOVA, the within-facility variance in SFR can be estimated by

$$s_{t,w}^2 = \frac{\sum_{i=1}^{N} [(n_i - 1)S_i^2]}{\sum_{i=1}^{N} (n_i - 1)},$$

and the total variation in SFR can be estimated by

$$s_t^2 = \frac{1}{n'(N-1)} \sum_{i=1}^N n_i (T_i - \bar{T})^2,$$

where  $n_i$  is the number of subjects in the *i*th facility,  $\overline{T} = \sum n_i T_i / \sum n_i$ , and

$$n' = \frac{1}{N-1} \left( \sum n_i - \sum n_i^2 / \sum n_i \right)$$

 $n' = \frac{1}{N-1} \left( \sum n_i - \sum n_i^2 \middle/ \sum n_i \right)$  is approximately the average facility size (number of patients per facility). Thus, the IUR =  $\sigma_b^2 / \left( \sigma_b^2 + \frac{1}{N-1} \right)$  $\sigma_{t,w}^2$ ) can be estimated by  $(s_t^2 - s_{t,w}^2)/s_t^2$ .

The reliability of SFR calculation only included facilities with at least 11 patients during the entire year.

The IUR is 0.736 which indicates that about 74% of the variation in the annual SFR can be attributed to between-facility differences in performance (signal) and about 26% to the within-facility variation (noise). The result of IUR testing suggests a high degree of reliability.

### **Validity Testing**

Face Validity: In 2015 a vascular access TEP was convened to provide input on the development of vascular access measures, and specifically input on exclusions for both catheter and fistula measures, and for fistula, risk adjustment factors to be considered. Ultimately, evaluation and selection of the clinical and patient risk factors for this measure was informed by the final TEP recommendations. The TEP recognized that while fistulas are preferred, an unintended consequence of a fistula measure that doesn't account for the patient's overall health status could harm patients by subjecting them to fistula surgery that is less likely to succeed or limit access to care for patients with more comorbidities. To accomplish this goal the TEP discussed adjusting the measure for conditions or scenarios where a graft may be an acceptable or preferred alternative to a fistula. The measure was reviewed and validated by the TEP.

Empirical validity was assessed using Poisson regression models to measure the association between facility level quintiles of performance scores and the 2014 Standardized Mortality Ratio (SMR, NQF

0369) and 2014 Standardized Hospitalization Ratio (SHR, NQF 1463). Facility-level performance scores were divided into quintiles (Q1 to Q5) and the relative risk (RR) of mortality (and hospitalization, separately) was calculated for each quintile, using the combined Q4 and Q5 as the reference group. Thus, a RR>1.0 would indicate a higher relative risk of mortality or hospitalization, compared to the highest performance score quintiles.

Quintiles of the performance scores were defined as follows:

Q1: 9.2%-<55.9%

Q2: 55.9%-<62.0%

Q3: 62.0-<67.4%

Q4\*: 67.4%-<73.4%

Q5\*: 73.4%-<97.5%

\*Q4 and Q5 as Reference

Results from the Poisson model indicated that the percent of patient-months with a fistula was significantly associated with the risks of mortality and hospitalization.

For the 2014 SMR, the relative risk of mortality increased as the performance measure quintile decreased from the reference group (combined Q4 and Q5) with the highest risk in quintile 1. For quintile 3, RR=1.03 (95% CI: 1.01, 1.05; p=0.003), quintile 2, RR=1.05 (95% CI: 1.03, 1.07; p<0.001), and quintile 1, RR=1.10 (95% CI: 1.08, 1.12; p<0.001).

Similarly for 2014 SHR, the relative risk of hospitalization increased as the performance measure quintile decreased from the reference group (combined Q4 and Q5) with the highest risk in quintile 1. For quintile 3, RR=1.07 (95% CI: 1.06, 1.07; p<0.001), quintile 2, RR=1.08 (95% CI: 1.08, 1.09; p<0.001), and quintile 1, RR=1.11 (95% CI: 1.11, 1.11; p<0.001).

These results of the Poisson regression suggest the predictive relationship of lower fistula use with higher mortality and hospitalization, as measured by the respective standardized mortality and hospitalization rates, and compared to facilities with higher fistula use.

<sup>\*1.</sup> Multiple data sources include CMS Consolidated Renal Operations in a Web-enabled Network (CROWNWeb), the CMS Annual Facility Survey (Form CMS-2744), Medicare dialysis and hospital payment records, the CMS Medical Evidence Form (Form CMS-2728), transplant data from the Organ Procurement and Transplant Network (OPTN), the Death Notification Form (Form CMS-2746), the Dialysis Facility Compare (DFC) and the Social Security Death Master File.

Unique patients are identified by using a combination of SSN, first name, surname, sex, Medicare claim number and birth date. A matching process is performed to ensure that minor typos and misspellings do not cause a patient record to fall out of their history. The matching process is able to successfully match 99.5% of patients. The remaining patients have incomplete or incorrect data that does not allow them to be matched.

<sup>\*2.</sup> Hospice information comes from the CMS Hospice file that contains final action claims submitted by Hospice providers. Once a beneficiary elects Hospice, all Hospice related claims will be found in this file, regardless if the beneficiary is in Medicare fee-for-service or in a Medicare managed care plan.

<sup>\*3.</sup> Medicare claims include Part A claims such as inpatient admissions and Part B claims such as outpatient claims (including dialysis claims) and physician services. Claims from providers, such as laboratories, that report diagnosis codes when testing for the presence of a condition are excluded.

<sup>\*4.</sup> Exclusion factors: A detailed list of ICD-9 diagnostic codes and HCPCS CPT codes used to identify comorbidities is included in this file (See Tab ICD-9 to 10 Exclusions).

<sup>\*5.</sup> Comorbidities were identified by combining prevalent comorbidities reported on all Medicare Claims in past 12 month and incident comorbidities reported on the Medical Evidence Form (CMS-2728). A detailed list of ICD-9 diagnostic codes and HCPCS CPT codes used to identify comorbidities from Medicare Claims are listed in Tab ICD-9 to 10 Adjustments)
